(Received January 7, 2019)

We adopt the Hartree–Fock (HF) method and the nucleon– Λ Tamm– Dancoff Approximation (N Λ TDA) to study the energy spectra of selected medium mass hypernuclei composed of a Λ hyperon bound to an even– even and odd–even nuclear cores. Our calculations are carried out using the YN LO potential plus the chiral potential NNLO_{sat}, which includes explicitly the 3-body NNN force. This component, while improving the r.m.s. radii of the nuclear cores and the relative distances between levels or group of levels of the hypernuclear spectra, strongly reduces the binding energies indicating that the inclusion of more complex configurations is badly needed.

DOI:10.5506/APhysPolBSupp.12.657

1. Introduction

The theoretical study of medium-mass and heavy hypernuclei may provide a guide for a better understanding of the hyperon–nucleon (YN) interaction at momentum scales not accessible in few-body systems.

Several methods, based mostly on phenomenological potentials, have been developed for this purpose. We mention the Skyrme Hartree–Fock model [1-3] and the relativistic mean field (RMF) model [4, 5].

J. Pokorný et al.

We started a project whose objective is to provide an *ab initio* description of medium-mass and heavy hypernuclei starting from modern realistic nucleon–nucleon and baryon–nucleon potentials, and to go beyond mean field by studying the role of complex many-body configurations. This final goal will eventually be reached by resorting to the Equation of Motion Phonon Method (EMPM). This method has been developed for nuclear structure studies [6] and extensively adopted for light and heavy even–even [7–10] and medium-mass odd–even nuclei [11–13].

The preliminary step of our approach consists in developing the Hartree– Fock (HF) method in the proton–neutron– Λ (p–n– Λ) scheme and, then, the nucleon– Λ Tamm–Dancoff Approximation (N Λ TDA) formalism. HF is suited for describing hypernuclei with one Λ particle bound to an even–even nuclear cores, while N Λ TDA allows us to study hypernuclei consisting of one Λ coupled to an odd–even nuclear cores [14].

Here, we have adopted the two methods to study the effect of the NNN part of the chiral NNLO_{sat} potential [15] on selected nuclei and hypernuclei. In particular, we compute the r.m.s. radii and binding energies of 12 C, 16 O, 40 Ca and 48 Ca, the single-particle energies of Λ in $^{13}_{\Lambda}$ C and $^{17}_{\Lambda}$ O and the energy spectra of $^{40}_{\Lambda}$ K and $^{48}_{\Lambda}$ K.

We do not take into account the effect of the Λ - Σ mixing. This issue is discussed in the conclusions.

2. Theoretical formalism

We adopted the intrinsic Hamiltonian

$$H = T + V^{NN} + V^{NNN} + V^{N\Lambda} - T_{\rm CM}, \qquad (1)$$

where T is the kinetic energy operator of nucleons and Λ , $T_{\rm CM}$ is the centreof-mass kinetic operator, and V^{NN} , V^{NA} , and V^{NNN} stand for the 2-body NN, the $N\Lambda$, and the 3-body NNN potentials, respectively.

The HF equations are

$$t_{ij}^{p} + \sum_{kl} V_{ikjl}^{pp} \rho_{lk}^{p} + \sum_{kl} V_{ikjl}^{pn} \rho_{lk}^{n} + \sum_{kl} V_{ikjl}^{p\Lambda} \rho_{lk}^{\Lambda} + \frac{1}{2} \sum_{klmn} V_{ikljmn}^{ppp} \rho_{mk}^{p} \rho_{nl}^{p} + \frac{1}{2} \sum_{klmn} V_{ikljmn}^{pnn} \rho_{mk}^{n} \rho_{nl}^{n} + \sum_{klmn} V_{ikljmn}^{ppn} \rho_{mk}^{p} \rho_{nl}^{n} = \varepsilon_{i}^{p} \delta_{ij} , \qquad (2)$$
$$t_{ij}^{n} + \sum_{kl} V_{ikjl}^{nn} \rho_{lk}^{n} + \sum_{kl} V_{kilj}^{pn} \rho_{lk}^{p} + \sum_{kl} V_{ikjl}^{n\Lambda} \rho_{lk}^{\Lambda} + \frac{1}{2} \sum_{klmn} V_{ikljmn}^{nnn} \rho_{mk}^{n} \rho_{nl}^{n} + \frac{1}{2} \sum_{klmn} V_{klimnj}^{ppn} \rho_{mk}^{p} \rho_{nl}^{p} + \sum_{klmn} V_{klimnj}^{pnn} \rho_{mk}^{p} \rho_{nl}^{n} = \varepsilon_{i}^{n} \delta_{ij} , \qquad (3)$$

Effect of a Realistic Three-body Force on the Energy Spectra ... 659

$$t_{ij}^{\Lambda} + \sum_{kl} V_{kilj}^{p\Lambda} \rho_{lk}^{p} + \sum_{kl} V_{kilj}^{n\Lambda} \rho_{lk}^{n} = \varepsilon_{i}^{\Lambda} \delta_{ij} , \qquad (4)$$

where ρ_{nm}^p , ρ_{nm}^n and ρ_{nm}^A are the density matrices for protons, neutrons and Λ , respectively.

The solution of the HF equations gives the single-particle energies ε_i^p , ε_i^n of the nucleons and yields the energies ε_i^{Λ} of the Λ hyperon bound to the even-even nuclear core [14].

The energy spectra of hypernuclei consisting of one Λ coupled to an odd–even nuclear cores are determined by solving the N Λ TDA eigenvalue equations. To this purpose, we solve separately the HF Eqs. (2)–(3) for the nucleons of the core and Eq. (4) for Λ . The energies and basis states so obtained enter the N Λ TDA eigenvalue equations

$$\sum_{ph} \left(\left(\varepsilon_p^{\Lambda} - \varepsilon_h^p \right) \delta_{pp'} \delta_{hh'} - V_{\bar{h}p'\bar{h}'p}^{p\Lambda} \right) r_{ph}^{\mu,p\Lambda} = \left(E_{\nu}^{p\Lambda} - E_{\rm HF} \right) r_{p'h'}^{\mu,p\Lambda}, \quad (5)$$

$$\sum_{ph} \left(\left(\varepsilon_p^{\Lambda} - \varepsilon_h^n \right) \delta_{pp'} \delta_{hh'} - V_{\bar{h}p'\bar{h}'p}^{n\Lambda} \right) r_{ph}^{\mu,n\Lambda} = \left(E_{\nu}^{n\Lambda} - E_{\rm HF} \right) r_{p'h'}^{\mu,n\Lambda} .$$
(6)

3. Calculation details and results

We have solved the HF equations starting from the harmonic oscillator (HO) basis with $\hbar\omega = 16$ MeV. As shown in Ref. [14], the convergence is satisfactory if we include all two-body and three-body matrix elements under the restrictions $\{|ij\rangle : 2n_i + l_i + 2n_j + l_j \leq N_{\max}\}$ and $\{|ijk\rangle : 2n_i + l_i + 2n_j + l_j \leq N_{\max}\}$ and $\{|ijk\rangle : 2n_i + l_i + 2n_j + l_j + 2n_k + l_k \leq N_{\max}\}$, with $N_{\max} = 12$.

3.1. HF calculation of ¹²C, ¹⁶O, ⁴⁰Ca and ⁴⁸Ca nuclear cores

The charge radii and binding energies of ¹²C, ¹⁶O, ⁴⁰Ca and ⁴⁸Ca are calculated by solving the HF Eqs. (2)–(3) for nucleons only ($\rho^A = 0$). These equations have been solved with and without the *NNN* component of the NNLO_{sat} potential [15].

The mean-square charged radius is given by

$$\left\langle r_{\rm ch}^2 \right\rangle = \left(1 - \frac{1}{A}\right) \frac{1}{Z} \left\langle r_p^2 \right\rangle + R_p^2 + \frac{N}{Z} R_n^2 + \frac{3\hbar^2}{4m_p^2 c^2} \,, \tag{7}$$

where $\langle r_p^2 \rangle = \int dr \ r^4 \rho_p(r)$ is the mean-square proton point radius, $R_p = 0.8775(51)$ fm, $R_n^2 = -0.1149(27)$ fm², and $\frac{3\hbar^2}{4m_p^2c^2} = 0.033$ fm² [15].

As shown in Table I, the charge radii r_{ch} calculated with the 2-body NN interaction only are too small. They are enhanced once the NNN force is included, in much better agreement with the experiments.

| | ^{A}X | NN | NN + NNN | exp. |
|--------------|-------------------|-------|----------|------|
| $r_{\rm ch}$ | | | | |
| | $^{12}\mathrm{C}$ | 2.13 | 2.52 | 2.47 |
| | ^{16}O | 2.19 | 2.77 | 2.70 |
| | 40 Ca | 2.58 | 3.54 | 3.48 |
| | 48 Ca | 2.55 | 3.57 | 3.47 |
| BE/A | | | | |
| | $^{12}\mathrm{C}$ | 4.59 | 1.70 | 7.68 |
| | ^{16}O | 7.36 | 2.66 | 7.98 |
| | 40 Ca | 11.65 | 2.31 | 8.55 |
| | ^{48}Ca | 12.95 | 1.93 | 8.67 |

The charge radii $r_{\rm ch} = \sqrt{\langle r_{\rm ch}^2 \rangle}$ [fm] and binding energies BE/A [MeV] of ¹²C, ¹⁶O, ⁴⁰Ca and ⁴⁸Ca calculated with NN and NN + NNN forces are compared with the experimental data (exp.) [18].

The effect of the 3-body NNN force on nuclear radii is caused by its repulsive character. This term, in fact, reduces strongly the binding energies of the nuclei under study (Table I), indicating that ground-state correlations are needed. The strong impact on the physical observables induced by more complex configurations emerges from the calculations using the NNLO_{sat} potential within a Coupled Cluster (CC) [15] and a SCGF approach [16].

The effect of the correlations has been also studied within the EMPM using the NNLO_{opt} potential [17].

This calculation, while affecting weakly the charge radii, yielded a contribution to the binding energy coming from two-phonon correlations comparable to the HF contribution.

On the ground of this EMPM calculation and the results obtained in Refs. [15, 16] with NNLO_{sat}, we expect that the ground-state correlations estimated within the EMPM should counterbalance the contribution coming from the strongly repulsive NNN part of the NNLO_{sat} potential, thereby filling to a large extent the gap with experiments.

3.2. Energy spectra of ${}^{13}_{\Lambda}C$, ${}^{17}_{\Lambda}O$, ${}^{40}_{\Lambda}K$ and ${}^{48}_{\Lambda}K$ hypernuclei

The hypernuclear energy spectra are calculated adopting the NA-NA channel of the chiral YN LO potential [19] with the regulator cut-off parameter $\lambda = 550$ MeV which yields for the hypernuclei under study binding energies of Λ closer to the empirical values.

The hypernuclear energy spectra depend almost linearly on λ for the employed YN LO potential [14]. Therefore, the relative distances among the energy levels are marginally affected by this parameter.

The NNN force affects strongly the single-particle levels of Λ in ${}^{13}_{\Lambda}C$ and ${}^{17}_{\Lambda}O$ (Fig. 1). In fact, the energy gaps are significantly reduced once the NNN force is included. The relative distances among the s-, p- and sd-major shells get closer to the empirical levels.

Fig. 1. The Λ single-particle energies ε_i^{Λ} in ${}^{13}_{\Lambda}$ C (a) and in ${}^{17}_{\Lambda}$ O (b) calculated with NN (I) and NN + NNN (II) interactions. The empirical energies (emp.) interpreted from the experimental measurements [20] are shown for comparison.

However, the calculated energy spectra are shifted upward in energy with respect to the experimental data. This clearly indicates that the correlations induced by more complex configurations are needed.

The too large splitting between $0p_{1/2}$ and $0p_{3/2}$ levels, especially in ${}^{13}_{\Lambda}$ C, may be reduced by including the $\Lambda - \Sigma$ mixing in the YN interaction not taken into account in the present calculation.

The NNN force affects strongly the spectra of ${}^{40}_{\Lambda}$ K and ${}^{48}_{\Lambda}$ K. As shown in Fig. 2, the N Λ TDA calculation yields multiplets of states which are far apart from each other when only the NN is used. The separations between these multiplets are drastically reduced by the NNN force.

Unfortunately, there are no experimental data for these two hypernuclei. An experiment for their production is planned at JLab [21]. Once more complex configurations are included through the EMPM, our calculations will provide the hypernuclear wave functions needed for the theoretical analysis of the data.

Fig. 2. (Colour on-line) The relative energies of ${}^{40}_{\Lambda}$ K (a) and ${}^{48}_{\Lambda}$ K (b) calculated with NN, and NN + NNN forces. The grey/red (black/blue) lines represent the states with the negative (positive) parity.

4. Conclusions

The results presented here put in evidence the strong effect of the NNN component of the NNLO_{sat} potential on nuclei and hypernuclei. In nuclei, the charge radii of ¹²C, ¹⁶O, ⁴⁰Ca, ⁴⁸Ca get close to the experimental values once the NNN force is included. Because of its repulsive nature, however, this force reduces considerably the NN contribution to the nuclear binding energies which are strongly underestimated.

The NNN force has a strong impact also on the hypernuclear energy spectra. It yields for ${}^{13}_{\Lambda}$ C and ${}^{17}_{\Lambda}$ O Λ single-particle energy separations close to the empirical ones apart from an overall upward shift of the levels.

An analogous effect is also observed in the energy spectra of ${}^{40}_{\Lambda}$ K and ${}^{48}_{\Lambda}$ K. The *NNN* force reduces significantly the gaps among the multiplets of levels. Such an effect may be tested in planned future experiments.

In order to bridge the gap with the experimental nuclear binding energies and to reproduce the absolute energies of hypernuclei, it is necessary to include more complex excitations. This will be achieved by resorting to the EMPM. The method derives and solves iteratively a set of equations of motion to generate an orthonormal basis of multiphonon states built of TDA phonons. Such a basis simplifies the structure of the Hamiltonian matrix and makes feasible its diagonalization in large configuration and phonon spaces. The diagonalization of the Hamiltonian in the multiphonon space so constructed produces highly correlated states, including the ground state. It takes into full account the Pauli principle and holds for any Hamiltonian.

We extend the method to hypernuclei with even-even and odd-even cores. In these two cases, we couple, respectively, the Λ states and the N Λ TDA phonons to the many particle-hole excitations of the nuclear cores.

Another important issue is the inclusion of the $\Lambda - \Sigma$ mixing in the YN LO interaction. We plan to include the $N\Lambda - N\Sigma$ part of the chiral LO YN interaction into the $N\Lambda - N\Lambda$ channel through the SRG transformation. Such a transformation has the effect of suppressing the $\Lambda - \Sigma$ mixing terms and generating thereby a 3-body YNN force to be added to the SRG transformed 2-body YN potential [22].
